

ABSTRACT OF THE DISCLOSURE

The communication system supports reservation of network resources. The base stations relay packets among the terminals, and perform priority control based on the priority set to the packets. In a terminal, the communication-managing table stores communication information of the terminal and a partner thereof. The packet-transmitting unit, setting priority to the packets, transmits the packets. When a link condition of the terminal changes, the link-managing unit updates, in order to prevent other terminals from quality deterioration, the priority of each of the packets whose source terminal is the terminal.
